1 Questions

1.1 Why do we even bother with hypergraphs?

All hypergraphs can be represented as regular graphs, and lots of tools already exist to handle graphs. When we want to express the wire length between two nodes, although it can easily be done using graph's edge weights, it is not expressible as a hypergraph's hyperedge weight, the hyperedge linking several nodes all connected with different wire lengths.

However, when tackling the partitioning problem, working with hypergraphs gives the vertices belonging to the same hyperedge a coherence. In the context of 3D ICs, we work with buses connecting blocks of gates, and we want them to be handled as such.

2 Recurring notions

2.1 Complexity

2.1.1 Non-deterministic Turing Machine

In this kind of Turing machines, the transition *rule* becomes a transition *function*. It means that at a given state, with a given symbol, it has many possible executions instead of just the one with a deterministic Turing machine. We can see that as the machine always taking the best possible guess, leading to a finishing state in the end, or the machine is branching into all the possible states from the point of decision.

2.1.2 NP

Acronym for "non-deterministic polynomial-time". A "yes"-instance can be found in polynomial-time by a non-deterministic Turing machine, and this

solution can be verified in polynomial-time by a deterministic Turing machine.

2.1.3 NP Hard

Acronym for “non-deterministic polynomial-time hard”.

Note: it has never been proven that there is no polynomial-time algorithm to solve those problems. Informally, it means that those problems are at least as hard as the hardest problems in NP.

2.1.4 NP Complete

A problem is NP complete when it is both NP and NP hard at the same time. Although the solution can be verified in polynomial time, there is no known algorithm to find this solution quickly. The problem to know if such algorithm exist is the “ $P = NP$ ” problem.

An NP-complete problem differs from a regular NP problem in the sense that a problem is NP-complete if every other problem in NP can be reduced to it.

2.1.5 $P=NP$

Problem asking if there exist polynomial time algorithm solving NP-complete problems (and by corollary all NP problems).

2.2 Optimization

2.2.1 Linear Programming

Optimization of a problem for which the requirements are represented using linear relationships.

2.2.2 Semidefinite Programming

Extends the linear programming problems, but using a positive semidefinite matrix as unknown value, instead of a vector of real integers.

3 Graph Partitioning

For a graph $G = (V, E)$, with V the set of n vertices and E the set of edges.

3.1 Balanced partition problem

In a (k, v) balanced partition problem, we want to partition G into k partitions of at most size $v \cdot \frac{n}{k}$, minimizing the capacity of the edges spanning multiple partitions [1]. This could allow to perform unbalanced partitioning based on the factor v ; if $v = 1$, all partitions will have the same size (considering $v \in \mathbb{N}_0$). However, it is still an upper bound, not an objective. All the partitions will have the same freedom in size, this does not enforce an asymmetry in the partitions size. This problem is also known as bicriteria approximation or resource augmentation.

3.2 Algorithms

[2]

3.2.1 Kernighan-Lin Algorithm

3.2.2 Fiduccia-Mattheyses Algorithm

3.2.3 Hagen-Kahng EIG Partitioning

3.3 Metaheuristics

Local Search Strategy A local search will look in the neighbourhood of the current solution for a better one. If there is nothing better in the direct vicinity of the position, just stop. As [3] says, this strategy is also known as "descent" strategy and is basically what was done in **phoney** when we tried to disbalance the energy repartition in the partitions, while keeping the area balanced.

The problem of this strategy is that it will get stuck in local minima. Escaping requires a deterioration of the solution, which is done by Simulated Annealing (SA) and Tabu Search (TS).

3.3.1 Simulated Annealing

[3] presents this heuristic kind of like the evolution of a local search. Instead of looking in the neighbourhood of the current solution, we pick one randomly. If it's better, keep it, otherwise we have a probability p to keep it, $(1 - p)$ to discard it. p is usually a Boltzmann-like distribution:

$$p(n) = \exp\left(-\frac{1}{T(n)}\Delta F_n\right)$$

with n the current step, $\Delta F_n = F(x) - F(x_n)$ the distance from the current solution, and $T(n)$ is what we could call the “temperature” by analogy with the annealing of steel. Each L steps, the temperature decreases, lowering the probability to accept a worse solution.

The stopping condition can be a number of steps from the beginning or a number a steps without enough improvement of the solution.

3.3.2 Tabu Search

A Tabu Search, as its name and [3] indicate, is based on a tabu of some sort. We will proceed like for a regular local search, the difference being that we establish a tabu list that prevents from cycling through the same solutions. In this list, we could simply store the L last visited solutions, forbidding them. But this is still not good enough and performs poorly in practice. An other approach is the forbid *movements*, *e.g.* changing some coordinate from 0 to 1. However, should a potential solution forbidden by the tabu list be so good according to some “aspiration level”, the tabu can be overlooked and the solution be chosen.

3.3.3 Genetic Algorithms

4 Manufacturing

4.1 Wafer to wafer

4.2 Die to die

4.3 Die to wafer

4.4 Monolithic

5 Electronic Design Automation

EDA is also known as “Electronic Computer-Aided Design” (ECAD).

5.1 Conferences

5.1.1 Design Automation Conference

San Diego, Anaheim and San Francisco in June.

- 5.1.2 International Conference on computer-Aided Design
- 5.1.3 Design Automation and Test in Europe
- 5.1.4 Asia and South Pacific Design Automation Conference
- 5.1.5 International Symposium on Quality Electronic Design

Glossary

SA Simulated Annealing.

TS Tabu Search.
